

Liars in the Miller-Rabin primality test

ARJUN YADAV

arjun@arjunyadav.net

Abstract

The Miller-Rabin primality test requires at least one witness to determine if any odd integer $n > 2$ is prime or not. This paper presents and explores the witnesses that lie the most in some range. When we consider three or four witnesses, all the top 500 worst witnesses in our ranges contain a zero. Zero also tends to be one of the worst witnesses when standing alone as a single witness or with another integer as two witnesses. The full results can be found as ancillary files on arXiv and in this paper's appendix. The code used, as well as the full results, can be found on GitHub.

I. INTRODUCTION

THE Miller-Rabin primality test was derived by Gary L. Miller and became a probabilistic primality test with Michael O. Rabin's "Probabilistic algorithm for testing primality" [1].

In this algorithm, we take any odd integer $n > 2$ and re-write n in the form $2^s \cdot d + 1$ (where s, d are positive integers and d is odd).

At this stage of the algorithm, we have to call one or more witnesses. We take one of those witnesses a where $0 < a < n$ and if any one of the following hold, then n is said to be a strong probable prime:

$$\begin{aligned} a &\equiv 1 \pmod{n} \\ a^{2^r \cdot d} &\equiv -1 \pmod{n} \text{ [for some } 0 \leq r < s \text{]} \end{aligned}$$

We'll be focusing on the first relation for the remainder of this paper.

A property worth noting about the Miller-Rabin primality test is that **if any one of the witnesses a does not hold true, then we can say with certainty that the number n inputted is composite, and if all witnesses a hold true,**

then we can say that n is a strong probable prime (with the accuracy depending on the number of cycles k and the choice of witnesses $[a_1, a_2, a_3, \dots]$).

II. CODE AND SUPPORTING MULTIPLE WITNESSES

Algorithm 1 Base Miller-Rabin primality test (supports a custom witness) [2]

```
 $n \leftarrow$  Odd integer  $n > 2$  to be tested.  
 $k \leftarrow$  Number of cycles that determines the accuracy of the test.  
 $a \leftarrow$  The custom witness.  
do  
  Write  $n - 1$  as  $2^s \cdot d$  with  $d$  being odd by factoring powers of two from  $n - 1$ .  
  repeat  $k$  times - (1):  
     $x \leftarrow a^d \pmod{n}$   
    if  $x = 1$  or  $x = n - 1$  then do next (1)  
    repeat  $s - 1$  times:  
       $x \leftarrow x^2 \pmod{n}$   
      if  $x = 1$  then return composite  
      else if  $x = n - 1$  then do next (1)  
    return composite  
return probably prime
```

To support multiple witnesses, we can loop through all inputted witnesses $[a_1, a_2, a_3, \dots]$, take a_1 , input it into the base Miller-Rabin primality test that supports a custom witness, store the result and repeat this process for the next witness a_2 and so forth till we reach the end of the list $[a_1, a_2, a_3, \dots]$.

With these results, we can use the property we noted earlier and **return composite** if **any one of the results returns composite** and **probably prime** if **all results return probably prime**.

Note that for the following pseudo code and for the results, the number of cycles k used in the base Miller-Rabin primality test function is ten.

Algorithm 2 Supporting multiple witnesses in the Miller-Rabin primality test [3]

```

 $n \leftarrow$  Odd integer  $n > 2$  to be tested.
 $[a_1, a_2, a_3, \dots] \leftarrow$  The array of custom witnesses.
Using a predefined base Miller-Rabin primality test function.
do
    Define an array called results.
    for  $a$  in  $[a_1, a_2, a_3]$ :
         $results \leftarrow$  Result of base Miller-Rabin primality test function with custom witness  $a$ .
    if composite in results then
        return composite
    return probably prime

```

III. ANALYSING THE RESULTS

i. Single witness

For the single witness results, we can see that **one is the worst liar** for $0 \leq n < 99$ and **zero is the worst liar** for the remaining ranges.

We can also observe that **even numbers and composite numbers tend to be some of the**

worst witnesses (see below pie charts).

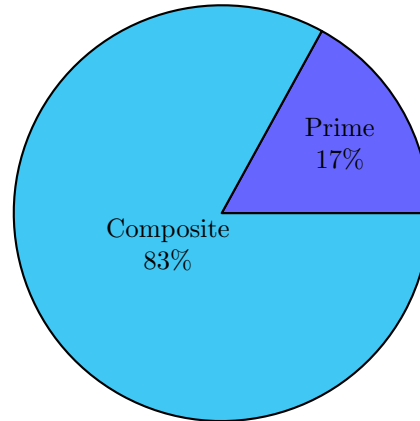

Figure 1: Distribution of top 100 worst witnesses on primality ($0 \leq n < 999$)

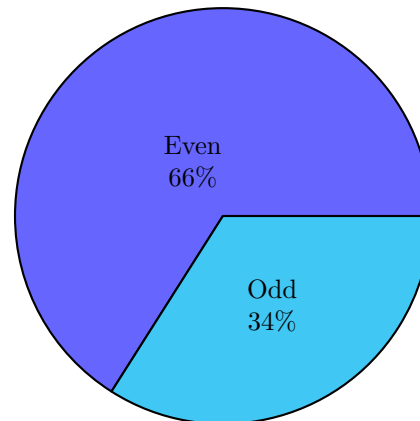

Figure 2: Distribution of top 100 worst witnesses on parity ($0 \leq n < 999$)

ii. Multiple witnesses

For this paper, **we analyzed two, three and four witnesses** using the itertools library for Python 3 [4]. However, **due to computational limitations, the results are quite predictable and repetitive**. Thus, we are analyzing the two, three and four witnesses results together.

In general, **zero is always present at least once in all the top 500 results for three and four witnesses**, it also occurs quite heavily in the two witnesses results. This is due to zero being coupled with every other possible witness in the given range.

IV. CONCLUSIONS AND ACKNOWLEDGEMENTS

This concludes our research on the worst witnesses in the Miller-Rabin primality test. Further research may return more exhaustive results and we encourage others with more computational power to find out more results in other ranges, possibly in more groups of witnesses (five, six, or more).

This research was inspired by Numberphile's video, "Witness Numbers (and the truthful 1,662,803)" featuring Matt Parker and Brady Haran [5]. This paper was reviewed by Devang Jhabakh Jai and Rikhav Shah, an undergraduate and graduate student respectively at the University of California, Berkeley and endorsed by Raghavendra N. Bhat, who recently graduated from the University of Illinois Urbana-Champaign.
